Multi-Factor Authentication and Single Sign-On

Login and Account Security

Fictional training documentation for a local RAG demonstration.

MFA basics

Multi-factor authentication adds a verification step beyond a password. Users should keep recovery options current and store backup codes securely if the product provides them.

Lost device

If a user loses access to their authenticator, use the official recovery option provided by CloudDesk or the organization's identity provider. Support must not bypass identity verification or accept a one-time code as proof of identity.

SSO accounts

When an organization enforces single sign-on, users generally authenticate through the organization's identity provider. Password resets and MFA changes may need to be completed there.

Troubleshooting

Confirm the correct organization sign-in page, system clock, browser, and identity-provider status. Capture the exact error and timestamp if the issue persists. Do not ask the user to disable security protections as a routine workaround.

Administrator role

An organization administrator may manage SSO configuration if permitted, but should follow the organization's approved identity process. Support should escalate configuration changes that could lock out multiple users.

Security incident

If the customer reports an unknown sign-in or suspected compromise, follow the suspicious-login guide and prioritize securing the account.
